# 1 Prerequisites

Required packages:

```
install.packages(c("compositions", "mvnfast", "quantmod", "plot3D", "sp"))
```

Loading packages:

```
require("classInt") # discretize numeric variable
require("compositions") # compositional data
require("ggplot2") # ggplot functions
require("mvnfast") # multivariate Student distribution
require("quantmod") # import financial data
require("plot3D") # plot distribution in 3D
require("RColorBrewer") # palette colors with R
require("rgdal") # import spatial data
require("sp") # spatial data
require("spdep") # spatial econometric modelling
```

Information about the current R session :

```
sessionInfo()
```

```
## R version 3.5.3 (2019-03-11)

# 2 Simulation study

This section demonstrates how to obtain the results presented in the section 3 of the article. We first present our functions which can be adapted to another framework different from our simulation process.

#### 2.1 Simulation of spatial multivariate Y

The function  $simu\_spatial\_multi\_y()$  simulates a multivariate Y of the form  $Y = Y\Gamma + WYR + X\beta + \epsilon$  where  $\epsilon$  follows either a multivariate Gaussian (**method\_simulate** = "N"), or the Independent multivariate Student (**method\_simulate** = "IT") distributions.

Input arguments are:

- **X**, the matrix of explanatory variables of size  $n \times K$ ,
- **beta\_true**, the  $\beta$  matrix of size  $K \times L$ :

$$\begin{pmatrix} \beta_{11} & \dots & \beta_{1L} \\ \beta_{21} & \dots & \beta_{2L} \\ \vdots & & \vdots \\ \beta_{K1} & \dots & \beta_{KL} \end{pmatrix}$$

- method\_simulate, the method of simulation (a character among "N", "IT"),
- Sigma, the matrix of size  $L \times L$ ,
- **GAMMA**, the matrix of size  $L \times L$ ,
- **RHO**, the matrix of size  $L \times L$ ,
- **W**, the matrix of size  $n \times n$ ,
- nu, for Student distribution only.

The function returns a matrix of size  $n \times L$ . To load the function:

```
source("./R/simu_spatial_multi_y.R")
```

#### 2.2 Examples

#### 2.2.1 Preparation of the data

Import the Midi-Pyrénées communes boundaries into R which was used in Goulard et al. (2017):

```
mapMAP <- readOGR(dsn = "contours", layer = "ADTCAN_region")</pre>
```

We convert the type of the identification units into numeric values:

```
mapMAP@data$CODE <- as.numeric(as.character(mapMAP@data$CODE))</pre>
```

The number of observations equals to n:

```
n <- nrow(mapMAP)
```

We consider one spatial weight matrix W, based on the 10-nearest neighbours and row-normalized. W is relatively sparse (96.5% of null values).

#### 2.2.2 Simulation of a multivariate SAR process

#### **2.2.2.1** Example when L = 2

We plan to simulate a multivariate Y of size L=2:

```
L_simu <- 2
```

We simulate the explanatory variables:

```
set.seed(1234)
x1 <- rnorm(n, 15, 3)
x2 <- rbinom(n, 100, 0.45)/100
x3 <- log(round(runif(n, 1, n),0))
x_simu <- cbind(rep(1, n), x1, x2, x3)
p_simu <- ncol(x_simu)</pre>
```

The  $\beta$  matrix is

$$\left(\begin{array}{cc} 5 & 2\\ 1/4 & -1\\ 6 & -3\\ 1 & 3 \end{array}\right),\,$$

the  $\Sigma$  matrix is

$$\left(\begin{array}{cc} 10 & 8 \\ 8 & 10 \end{array}\right),$$

the  $\Gamma$  matrix is

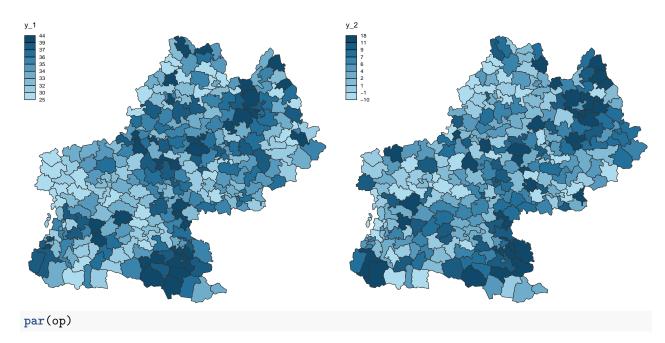

$$\left(\begin{array}{cc} 0 & 0 \\ 0 & 0 \end{array}\right),$$

and the R matrix is

$$\left(\begin{array}{cc} 0.75 & 0.1 \\ 0.3 & 0.15 \end{array}\right).$$

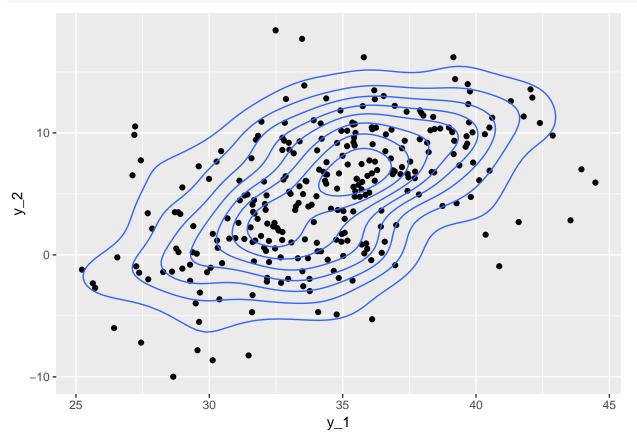

We simulate the process:

We plot the two component of Y on the map:

We also plot the joint distribution:

```
y_N_df <- data.frame(y_1 = y_N[, 1], y_2 = y_N[, 2])
sp <- ggplot(y_N_df, aes(x = y_1, y = y_2)) +
    geom_point()
sp + geom_density_2d()</pre>
```

#### **2.2.2.2** Example when L = 3

We simulate another multivariate sample when L=3.

We keep the same explanatatory variable X. However, the  $\beta$  matrix is now equal to:

$$\left(\begin{array}{cccc}
5 & 2 & 10 \\
1/4 & -1 & 4 \\
6 & -3 & -5 \\
1 & 3 & 5
\end{array}\right)$$

and the  $\Sigma$  matrix is

$$\left(\begin{array}{ccc}
12 & 10 & 10 \\
10 & 15 & 10 \\
10 & 10 & 20
\end{array}\right)$$

The  $\Gamma$  matrix is

$$\left(\begin{array}{ccc}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right)$$

```
GAMMA_3 <- matrix(c(0, 0, 0, 0, 0, 0, 0, 0),

nrow = L_3, ncol = L_3)
```

The  $\rho$  matrix is

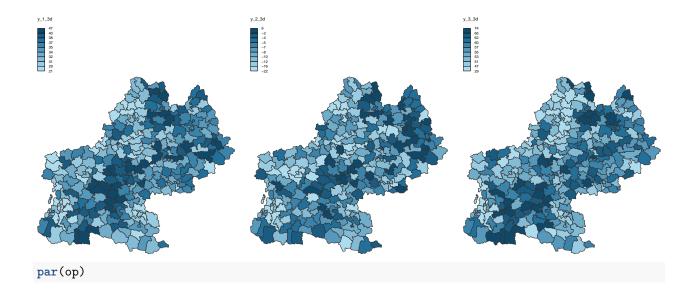

$$\left(\begin{array}{ccc} 0.75 & 0.1 & 0.1 \\ 0.1 & 0.25 & 0.1 \\ 0.1 & 0.1 & 0.8 \end{array}\right)$$

```
RHO_3 <- matrix(c(0.5, 0.1, 0.1, 0.1, 0.35, 0.1, 0.1, 0.1, 0.4),

nrow = L_3, ncol = L_3)
```

#### Simulation of a "N" distribution

We plot the three component of Y on the map:

# 3 Estimation

#### 3.1 Estimation of the parameters by a 2SLS method

The function  $estimate\_spatial\_multi\_N()$  estimates the coefficients associated to the multivariate Gaussian SAR model. The algorithm is based on Kelejian and Prucha (1998).

Input arguments are:

- Y, a matrix of size  $n \times L$
- X, a matrix of explanatory variables of size  $n \times K$ ,
- **W**, a spatial weight matrix of size  $n \times n$ ,
- GAMMA\_esti, a boolean which indicates if we estimate or nor the parameter associated to  $\Gamma$ .

The function returns a list with:

- the estimate of the  $\beta$  parameters
- the estimate of the  $\Gamma$  matrix
- the estimate of the R matrix
- the estimate of the  $\Sigma$  matrix

To load the function:

```
source("./R/estimate_spatial_multi_N.R")
source("./R/estimate_spatial_multi_gen_N.R")
```

#### 3.1.1 Examples:

Simulated data when L=2

### 3.2 Application to the real data

We first load the data:

```
source("R/preparation_base_ilr.R")
```

Then, we plot the data.

We prepare the explanatory variables:

#### 3.2.1 Multivariate Gaussian model

We estimate first a multivariate gaussian model by using the lm() function.

```
res_N <- lm(Ye ~ Xe - 1)
```

Then, we look the spatial distribution of the residuals. For this, we first compute a spatial weight matrix based on the 4-nearest neighbours.

We test the spatial autocorrelation in the residuals component by component:

```
moran.mc(residuals(res_N)[, 1], listw = W_listw, nsim = 1000)
```

```
##
## Monte-Carlo simulation of Moran I
##
## data: residuals(res_N)[, 1]
## weights: W_listw
## number of simulations + 1: 1001
##
## statistic = 0.25723, observed rank = 1001, p-value = 0.000999
## alternative hypothesis: greater
```

```
moran.mc(residuals(res_N)[, 2], listw = W_listw, nsim = 1000)
   Monte-Carlo simulation of Moran I
##
##
## data: residuals(res_N)[, 2]
## weights: W_listw
## number of simulations + 1: 1001
## statistic = 0.24837, observed rank = 1001, p-value = 0.000999
## alternative hypothesis: greater
We plot the residuals:
dep.2015.spdf@data[, c("res_y_1", "res_y_2")] <- residuals(res_N)</pre>
library("cartography")
op <- par(mfrow = c(1, 2), oma = c(0, 0, 0, 0), mar = c(0, 0, 1, 0))
choroLayer(spdf = dep.2015.spdf, var = "res_y_1", legend.pos = "topleft",
           method = "quantile", legend.values.rnd = 2)
choroLayer(spdf = dep.2015.spdf, var = "res_y_2", legend.pos = "topleft",
           method = "quantile", legend.values.rnd = 2)
res v 1
                                                 res v 2
                                                   0.54
0.28
0.21
0.14
0.05
par(op)
We estimate a multivariate gaussian SAR model by using the lm() function.
(res_sar_N <- estimate_spatial_multi_N(Ye, Xe, W_dep, GAMMA_esti = F))</pre>
